# Section 1

## Kähler case

Let  $(M, \omega, J)$  be a Kähler manifold. The so-called Lefschetz operator is defined as follows:

$$L: H^k(M) \longrightarrow H^{k+2}(M), \quad L([\alpha]) = [\omega \wedge \alpha].$$

Let  $(M, \omega, J)$  be a Kähler manifold. The so-called Lefschetz operator is defined as follows:

$$L: H^k(M) \longrightarrow H^{k+2}(M), \quad L([\alpha]) = [\omega \wedge \alpha].$$

### Theorem (Hard Lefschetz theorem)

*Let  $(M^n, \omega, J)$  be a compact Kähler manifold. The homomorphism*

$$L^r: H^{n-r}(M) \longrightarrow H^{n+r}(M), \quad L([\alpha]) = [\omega \wedge \alpha].$$

*is an isomorphism for all  $r \geq 0$ .*

Let  $\Lambda: H^k(M) \rightarrow H^{k-2}(M)$  be the formal adjoint of  $L$ . A  $k$ -form  $\alpha$  is called **effective (or primitive)**, if  $\Lambda\alpha = 0$ . Let  $P^k$  be the space of all effective  $k$ -forms.

Let  $\Lambda: H^k(M) \rightarrow H^{k-2}(M)$  be the formal adjoint of  $L$ . A  $k$ -form  $\alpha$  is called **effective (or primitive)**, if  $\Lambda\alpha = 0$ . Let  $P^k$  be the space of all effective  $k$ -forms.

The hard Lefschetz theorem then implies the following isomorphism, which is **the Lefschetz decomposition**:

$$H^k(M) = \bigoplus_{r \geq 0} L^r(P^{k-2r}).$$

## Section 2

# Quaternionic case

Let  $I, J, K$  be three almost complex structures on a  $4n$ -dimensional manifold  $M$ , such that they satisfy  $I \circ J = K$  and its cyclic permutations, then the ordered triple  $H = (I, J, K)$  on  $M$  is called an **almost hypercomplex structure**.

Let  $I, J, K$  be three almost complex structures on a  $4n$ -dimensional manifold  $M$ , such that they satisfy  $I \circ J = K$  and its cyclic permutations, then the ordered triple  $H = (I, J, K)$  on  $M$  is called an **almost hypercomplex structure**. An **almost quaternionic structure** on the manifold  $M$  is a rank 3 vector subbundle  $Q$  of the endomorphism bundle  $End(TM)$  which locally is spanned by an almost hypercomplex structure  $H = (I, J, K)$  which are transformed by  $SO(3)$  on the their respective domains of existence.

Let  $I, J, K$  be three almost complex structures on a  $4n$ -dimensional manifold  $M$ , such that they satisfy  $I \circ J = K$  and its cyclic permutations, then the ordered triple  $H = (I, J, K)$  on  $M$  is called an **almost hypercomplex structure**. An **almost quaternionic structure** on the manifold  $M$  is a rank 3 vector subbundle  $Q$  of the endomorphism bundle  $End(TM)$  which locally is spanned by an almost hypercomplex structure  $H = (I, J, K)$  which are transformed by  $SO(3)$  on their respective domains of existence. A **quaternionic structure** on the manifold  $M$  is an almost quaternionic structure  $Q$  such that there exists a torsionless connection  $\nabla$  whose extension to  $End(TM)$  preserves the subbundle  $Q$ , i.e.  $\nabla Q \subset Q$ .

Let  $I, J, K$  be three almost complex structures on a  $4n$ -dimensional manifold  $M$ , such that they satisfy  $I \circ J = K$  and its cyclic permutations, then the ordered triple  $H = (I, J, K)$  on  $M$  is called an **almost hypercomplex structure**. An **almost quaternionic structure** on the manifold  $M$  is a rank 3 vector subbundle  $Q$  of the endomorphism bundle  $End(TM)$  which locally is spanned by an almost hypercomplex structure  $H = (I, J, K)$  which are transformed by  $SO(3)$  on the their respective domains of existence. A **quaternionic structure** on the manifold  $M$  is an almost quaternionic structure  $Q$  such that there exists a torsionless connection  $\nabla$  whose extension to  $End(TM)$  preserves the subbundle  $Q$ , i.e.  $\nabla Q \subset Q$ . On an almost quaternionic manifold  $(M, Q)$  the metric  $g$  is **quaternion Hermitian** if it is Hermitian with respect to the local basis  $(I, J, K)$  of  $Q$ .

Let  $I, J, K$  be three almost complex structures on a  $4n$ -dimensional manifold  $M$ , such that they satisfy  $I \circ J = K$  and its cyclic permutations, then the ordered triple  $H = (I, J, K)$  on  $M$  is called an **almost hypercomplex structure**. An **almost quaternionic structure** on the manifold  $M$  is a rank 3 vector subbundle  $Q$  of the endomorphism bundle  $End(TM)$  which locally is spanned by an almost hypercomplex structure  $H = (I, J, K)$  which are transformed by  $SO(3)$  on the their respective domains of existence. A **quaternionic structure** on the manifold  $M$  is an almost quaternionic structure  $Q$  such that there exists a torsionless connection  $\nabla$  whose extension to  $End(TM)$  preserves the subbundle  $Q$ , i.e.  $\nabla Q \subset Q$ . On an almost quaternionic manifold  $(M, Q)$  the metric  $g$  is **quaternion Hermitian** if it is Hermitian with respect to the local basis  $(I, J, K)$  of  $Q$ . It is **quaternion Kähler** if it is quaternion Hermitian and  $Q$  is  $\nabla$ -parallel for the Levi-Civita connection of  $g$ .

Quaternion Kähler manifolds are Riemannian manifolds  $(M, g)$  of real dimension  $4n$  whose holonomy group can be reduced to  $Sp(n).Sp(1)$ .

Quaternion Kähler manifolds are Riemannian manifolds  $(M, g)$  of real dimension  $4n$  whose holonomy group can be reduced to  $Sp(n).Sp(1)$ . In dimension  $4(n = 1)$  this condition means only that the manifold is Riemannian as  $Sp(1).Sp(1) = SO(4)$ . Therefore this condition is meaningful for  $n \geq 2$ .

## Section 3

# Foliation

# Foliated manifolds

Let  $(M, \mathcal{F})$  be a Riemannian foliation. Then it is defined by a cocycle  $\mathcal{U} = \{U_i, f_i, k_{ij}\}_{i,j \in I}$  that is modeled on a Riemannian manifold  $(N, \bar{g})$  such that

- 1  $f_i : U_i \rightarrow N$  is a submersion with connected fibers;
- 2  $k_{ij} : f_j(U_i \cap U_j) \rightarrow f_i(U_i \cap U_j)$  are local isometries of  $(N, \bar{g})$ ;
- 3  $f_i = k_{ij} f_j$  on  $U_i \cap U_j$ .

## Definition

A foliation  $\mathcal{F}$  is transversely quaternion Kähler if it is defined by a cocycle  $\mathcal{U} = \{U_i, f_i, g_{ij}\}_{i,j \in I}$  modeled on a quaternion Kähler manifold  $(N_0, g_0, Q_0)$  and the local diffeomorphisms  $g_{ij}$  are local automorphisms of the quaternion Kähler structure of  $(N_0, g_0, Q_0)$ , i.e., the  $g_{ij}$  are local isometries and the induced mappings  $\tilde{g}_{ij}$  of  $\text{End}(TN_0)$  preserve the subbundle  $Q_0$  of rank 3.

In the language of foliated structures this condition can be formulated as follows.

In the language of foliated structures this condition can be formulated as follows. Let  $N(M, \mathcal{F}) = TM/T\mathcal{F}$  be the normal bundle of the foliation  $\mathcal{F}$ .

In the language of foliated structures this condition can be formulated as follows. Let  $N(M, \mathcal{F}) = TM/T\mathcal{F}$  be the normal bundle of the foliation  $\mathcal{F}$ . The vector bundle  $End(N(M, \mathcal{F}))$  admits the natural foliation  $\mathcal{F}_{End}$  of dimension  $p$  which is defined by a cocycle  $\mathcal{F}_{End} = \{V_i, \tilde{f}_i, \tilde{g}_{ij}\}_{i,j \in I}$  modeled on  $End(TN_0)$  where  $\tilde{f}(A) = df \circ A \circ (df|_{N(M, \mathcal{F})})^{-1}$ . With this in mind we can define a foliated quaternion Kähler structure.

## Definition

A foliated quaternion Kähler structure on a foliated Riemannian manifold  $(M, \mathcal{F})$  is given by the following data:

- 1  $g$  is a foliated Riemannian metric in  $N(M, \mathcal{F})$ ;
- 2 a 3-dimensional foliated subbundle  $Q$  of  $End(N(M, \mathcal{F}))$  which is locally spanned by 3 almost complex foliated structures;
- 3 the metric  $g$  is Hermitian with respect to these local almost complex structures;
- 4 the subbundle  $Q$  is parallel with respect to the foliated Levi-Civita connection of  $g$ .

Therefore a foliated quaternion Kähler structure on a foliated Riemannian manifold  $(M, \mathcal{F})$  will be denoted by  $(M, \mathcal{F}, g, Q)$ .

Therefore a foliated quaternion Kähler structure on a foliated Riemannian manifold  $(M, \mathcal{F})$  will be denoted by  $(M, \mathcal{F}, g, Q)$ . At each point  $x \in U_i$ , there exist 3 foliated almost complex structures  $I_x, J_x$ , and  $K_x$  on an open neighbourhood  $U_x$ .

Therefore a foliated quaternion Kähler structure on a foliated Riemannian manifold  $(M, \mathcal{F})$  will be denoted by  $(M, \mathcal{F}, g, Q)$ . At each point  $x \in U_i$ , there exist 3 foliated almost complex structures  $I_x, J_x$ , and  $K_x$  on an open neighbourhood  $U_x$ . Then on  $U_x$  we define the 2-forms

$$\Omega_I(u, v) = g(Iu, v), \quad \Omega_J(u, v) = g(Ju, v), \quad \text{and} \quad \Omega_K(u, v) = g(Ku, v),$$

where  $u, v \in N(M, \mathcal{F})$ .

Therefore a foliated quaternion Kähler structure on a foliated Riemannian manifold  $(M, \mathcal{F})$  will be denoted by  $(M, \mathcal{F}, g, Q)$ . At each point  $x \in U_i$ , there exist 3 foliated almost complex structures  $I_x, J_x$ , and  $K_x$  on an open neighbourhood  $U_x$ . Then on  $U_x$  we define the 2-forms

$$\Omega_I(u, v) = g(Iu, v), \quad \Omega_J(u, v) = g(Ju, v), \quad \text{and} \quad \Omega_K(u, v) = g(Ku, v),$$

where  $u, v \in N(M, \mathcal{F})$ .

The 4-form  $\Omega$

$$\Omega = \Omega_I \wedge \Omega_I + \Omega_J \wedge \Omega_J + \Omega_K \wedge \Omega_K$$

is well-defined, i.e., it is independent of the choice of the structures  $I, J$ , and  $K$ .

## Section 4

# Hodge theory for basic forms

On a foliated Riemannian manifold  $(M, g, \mathcal{F})$  the set of all basic  $k$ -forms is

$$A^k(M, \mathcal{F}) = \{\alpha \in A^k(M) : i_X \alpha = 0, i_X d\alpha = 0, \text{ for all vectors } X \in T\mathcal{F}\},$$

which is a subcomplex of  $A^k(M)$  and we denote its cohomology by  $H^k(M, \mathcal{F})$ .

On a foliated Riemannian manifold  $(M, g, \mathcal{F})$  the set of all basic  $k$ -forms is

$$A^k(M, \mathcal{F}) = \{\alpha \in A^k(M) : i_X \alpha = 0, i_X d\alpha = 0, \text{ for all vectors } X \in T\mathcal{F}\},$$

which is a subcomplex of  $A^k(M)$  and we denote its cohomology by  $H^k(M, \mathcal{F})$ .

The restriction of the bundle-like metric to the normal bundle of the foliation of the Riemannian foliated manifold  $(M, g, \mathcal{F})$  defines  $\bar{*}$  operator,

$$\bar{*}: A^k(M, \mathcal{F}) \rightarrow A^{4n-k}(M, \mathcal{F}).$$

On the Riemannian manifold  $(M, g)$  we have the  $*$ -operator acting on the complex of smooth forms:

$$*: A^k(M) \rightarrow A^{m-k}(M).$$

On the Riemannian manifold  $(M, g)$  we have the  $*$ -operator acting on the complex of smooth forms:

$$*: A^k(M) \rightarrow A^{m-k}(M).$$

On the subcomplex  $A^k(M, \mathcal{F})$  of basic forms these two operators are related by the formula

$$\bar{*}\alpha = (-1)^{p(q-k)} * (\alpha \wedge \chi_{\mathcal{F}}),$$

for any  $\alpha \in A^k(M, \mathcal{F})$ , where  $\chi_{\mathcal{F}}$  is the volume form of leaves.

In  $A^k(M, \mathcal{F})$  we have the standard scalar product

$$\langle \alpha, \beta \rangle_{\mathcal{F}} = \int_M \alpha \wedge \bar{*}\beta \wedge \chi_{\mathcal{F}},$$

which is the restriction of the standard scalar product on  $A^k(M)$ .

In  $A^k(M, \mathcal{F})$  we have the standard scalar product

$$\langle \alpha, \beta \rangle_{\mathcal{F}} = \int_M \alpha \wedge \bar{*}\beta \wedge \chi_{\mathcal{F}},$$

which is the restriction of the standard scalar product on  $A^k(M)$ .  
A Riemannian foliation on a compact manifold is said to be **taut** if there exists a Riemannian metric that makes all its leaves minimal submanifolds.

In  $A^k(M, \mathcal{F})$  we have the standard scalar product

$$\langle \alpha, \beta \rangle_b = \int_M \alpha \wedge \bar{*}\beta \wedge \chi_{\mathcal{F}},$$

which is the restriction of the standard scalar product on  $A^k(M)$ . A Riemannian foliation on a compact manifold is said to be **taut** if there exists a Riemannian metric that makes all its leaves minimal submanifolds. Tautness is characterized by the nonvanishing of the top dimensional basic cohomology, i.e.,  $H^q(M, \mathcal{F}) \neq 0$ . In this case we say that the foliation is **cohomologically taut**. In fact, this Riemannian metric can be chosen to be bundle-like.

The formal adjoint  $\delta_b$  of  $d$  in the complex  $A^k(M, \mathcal{F})$  with the scalar product  $\langle \cdot, \cdot \rangle_b$  is the operator

$$\delta_b = (d - \kappa \wedge)^{\bar{*}} : A^k(M, \mathcal{F}) \rightarrow A^{k-1}(M, \mathcal{F}),$$

where  $\kappa$  is the mean curvature form of the leaves,

The formal adjoint  $\delta_b$  of  $d$  in the complex  $A^k(M, \mathcal{F})$  with the scalar product  $\langle \cdot, \cdot \rangle_b$  is the operator

$$\delta_b = (d - \kappa \wedge)^{\bar{*}} : A^k(M, \mathcal{F}) \rightarrow A^{k-1}(M, \mathcal{F}),$$

where  $\kappa$  is the mean curvature form of the leaves, and

$$(d - \kappa \wedge)^{\bar{*}}(\beta) = (-1)^{q(k+1)+1} \bar{*}(d - \kappa) \bar{*}\beta,$$

for any  $\beta \in A^k(M, \mathcal{F})$ .

The formal adjoint  $\delta_b$  of  $d$  in the complex  $A^k(M, \mathcal{F})$  with the scalar product  $\langle \cdot, \cdot \rangle_b$  is the operator

$$\delta_b = (d - \kappa \wedge)^{\bar{*}} : A^k(M, \mathcal{F}) \rightarrow A^{k-1}(M, \mathcal{F}),$$

where  $\kappa$  is the mean curvature form of the leaves, and

$$(d - \kappa \wedge)^{\bar{*}}(\beta) = (-1)^{q(k+1)+1} \bar{*}(d - \kappa) \bar{*}\beta,$$

for any  $\beta \in A^k(M, \mathcal{F})$ . If the leaves of  $\mathcal{F}$  are minimal submanifolds for the bundle-like metric  $g$ , then  $\kappa = 0$  and  $\delta_b = d^{\bar{*}}$ .

The formal adjoint  $\delta_b$  of  $d$  in the complex  $A^k(M, \mathcal{F})$  with the scalar product  $\langle \cdot, \cdot \rangle_b$  is the operator

$$\delta_b = (d - \kappa \wedge)^{\bar{*}}: A^k(M, \mathcal{F}) \rightarrow A^{k-1}(M, \mathcal{F}),$$

where  $\kappa$  is the mean curvature form of the leaves, and

$$(d - \kappa \wedge)^{\bar{*}}(\beta) = (-1)^{q(k+1)+1} \bar{*}(d - \kappa) \bar{*}\beta,$$

for any  $\beta \in A^k(M, \mathcal{F})$ . If the leaves of  $\mathcal{F}$  are minimal submanifolds for the bundle-like metric  $g$ , then  $\kappa = 0$  and  $\delta_b = d^{\bar{*}}$ . We define the basic Laplacian as

$$\Delta_b = \delta_b d + d \delta_b$$

The formal adjoint  $\delta_b$  of  $d$  in the complex  $A^k(M, \mathcal{F})$  with the scalar product  $\langle \cdot, \cdot \rangle_b$  is the operator

$$\delta_b = (d - \kappa \wedge)^{\bar{*}} : A^k(M, \mathcal{F}) \rightarrow A^{k-1}(M, \mathcal{F}),$$

where  $\kappa$  is the mean curvature form of the leaves, and

$$(d - \kappa \wedge)^{\bar{*}}(\beta) = (-1)^{q(k+1)+1} \bar{*}(d - \kappa) \bar{*}\beta,$$

for any  $\beta \in A^k(M, \mathcal{F})$ . If the leaves of  $\mathcal{F}$  are minimal submanifolds for the bundle-like metric  $g$ , then  $\kappa = 0$  and  $\delta_b = d^{\bar{*}}$ . We define the basic Laplacian as

$$\Delta_b = \delta_b d + d \delta_b$$

A basic form  $\alpha$  is called **harmonic** iff  $\Delta_b \alpha = 0$ . The basic Hodge theorem for compact Riemannian foliated manifolds asserts that  $\alpha$  is harmonic iff  $d\alpha = 0 = \delta_b \alpha$ .

Using the 4-form  $\Omega$ , we define  $L$  and  $\Lambda$  operators on the complex  $A^*(M, \mathcal{F})$ :

$$L: A^k(M, \mathcal{F}) \rightarrow A^{k+4}(M, \mathcal{F}); \quad L(\alpha) = \Omega \wedge \alpha$$

$$\Lambda: A^k(M, \mathcal{F}) \rightarrow A^{k-4}(M, \mathcal{F}); \quad \Lambda(\alpha) = \bar{*}(\Omega \wedge \bar{*}\alpha)$$

Basic forms that are annihilated by  $\Lambda$  are called **effective**.

On a compact manifold with a taut foliation one can define scalar products  $\langle \cdot, \cdot \rangle$  and  $\langle \cdot, \cdot \rangle_b$  on  $A^k(M)$  and  $A^k(M, \mathcal{F})$ , respectively, as

$$1 \quad \langle \omega, \omega' \rangle = \int_M *(\omega \wedge *\omega') = \int_M \omega \wedge *\omega',$$

$$2 \quad \langle \omega, \omega' \rangle_b = \int_M \bar{*}(\omega \wedge \bar{*}\omega') = \int_M \omega \wedge \bar{*}\omega' \wedge \chi_{\mathcal{F}}.$$

On a compact manifold with a taut foliation one can define scalar products  $\langle \cdot, \cdot \rangle$  and  $\langle \cdot, \cdot \rangle_b$  on  $A^k(M)$  and  $A^k(M, \mathcal{F})$ , respectively, as

$$\mathbf{1} \quad \langle \omega, \omega' \rangle = \int_M *(\omega \wedge *\omega') = \int_M \omega \wedge *\omega',$$

$$\mathbf{2} \quad \langle \omega, \omega' \rangle_b = \int_M \bar{*}(\omega \wedge \bar{*}\omega') = \int_M \omega \wedge \bar{*}\omega' \wedge \chi_{\mathcal{F}}.$$

Using this scalar product we have for any  $\omega \in A^k(M, \mathcal{F})$  and  $\omega' \in A^{k+4}(M, \mathcal{F})$

$$\langle L\omega, \omega' \rangle_b = \langle \omega, \Lambda\omega' \rangle_b.$$

## Theorem (M., R. Wolak)

*Let  $(M, g, \mathcal{F})$  be a  $(4n + p)$ -dimensional Riemannian foliated manifold whose  $p$ -dimensional foliation  $\mathcal{F}$  is transversely quaternion Kähler. Let  $\omega$  be a basic differential form on  $(M, \mathcal{F})$  of degree  $p \leq n + 1$ . Then*

$$\omega = \sum_{i=0}^{[p/4]} L^i \omega_e^{p-4i}$$

*where  $\omega_e^k$  is an effective basic  $k$ -form.*

Let  $(M, \mathcal{F})$  be a compact Riemannian foliated manifold. Assume that

- 1) its foliated normal bundle  $(N(M, \mathcal{F}), \mathcal{F}_N)$  admits a reduction to a connected subgroup  $G$  of  $O(q)$ ,

Let  $(M, \mathcal{F})$  be a compact Riemannian foliated manifold. Assume that

- 1) its foliated normal bundle  $(N(M, \mathcal{F}), \mathcal{F}_N)$  admits a reduction to a connected subgroup  $G$  of  $O(q)$ ,
- 2) the corresponding foliated  $G$ -reduction  $B((M, \mathcal{F}), G, \mathcal{F}_G)$  of the foliated frame bundle  $L((M, \mathcal{F}), \mathcal{F}_L)$  admits a foliated connection without torsion.

The fiber bundle  $\bigwedge^k N_x(M, \mathcal{F})^*$  can be understood as the associated bundle of  $L((M, \mathcal{F}), \mathcal{F}_L)$  with the standard fiber  $\bigwedge^k(R^{q*})$ . The space of sections of this bundle we denote by  $A^k(N)$ . Since the normal frame bundle  $L(M, \mathcal{F})$  is foliated, the foliation  $\mathcal{F}_L$  induces a foliation  $\mathcal{F}_L^k$  of the fiber bundle  $\bigwedge^k N_x(M, \mathcal{F})^*$ . The space of  $k$ -basic forms  $A^k(M, \mathcal{F})$  is a subspace of  $A^k(N)$ . If the normal frame bundle  $L(M, \mathcal{F})$  admits a foliated  $G$ -reduction  $B((M, \mathcal{F}), G, \mathcal{F}_G)$ , the bundle  $\bigwedge^k N_x(M, \mathcal{F})^*$  can be understood as the associated fiber bundle of  $B((M, \mathcal{F}), G, \mathcal{F}_G)$  with the standard fiber  $\bigwedge^k(R^{q*})$ . The natural induced foliations coincide. Let  $W \subset \bigwedge^k(R^{q*})$  be an invariant subspace of  $\bigwedge^k(R^{q*})$  under the standard action of  $G$ . There is the standard scalar product on  $\bigwedge^k(R^{q*})$  for which the induced action of  $G$  is isometric.

The associated fiber bundle  $\mathcal{W}$  of  $B((M, \mathcal{F}), G, \mathcal{F}_G)$  with the standard fiber  $W$  can be understood as a foliated vector subbundle of the foliated vector bundle  $(\bigwedge^k N_x(M, \mathcal{F})^*, \mathcal{F}_L^k)$ . Therefore a  $k$ -differential form  $\alpha$  which corresponds to a section of  $\mathcal{W}$  is said to be of type  $W$ . The space of these  $\mathcal{W}$ -valued sections we denote also by  $\mathcal{W}$ . The projection  $P_W: A^k(N) \rightarrow \mathcal{W}$  sends basic forms into basic forms as the operation is done point by point. Next we show that the result of S.S. Chern can be reformulated for the basic Laplacian  $\Delta_b$ .

## Proposition (M., R. Wolak)

Let  $W \subset \bigwedge^k(R^{q*})$  be an invariant subspace of  $\bigwedge^k(R^{q*})$  under the standard action of  $G$ ,  $P_W$  be the projection  $P_W: A^k(M, \mathcal{F}) \rightarrow W$  and  $\Delta_b$  be the basic Laplacian, then

$$P_W \Delta_b = \Delta_b P_W.$$

Moreover, let  $W_1, \dots, W_s$  be irreducible invariant subspaces of  $\bigwedge^k(R^{q*})$  for the action of the group  $G$ . Then if  $\alpha$  is a harmonic basic  $k$ -form, the  $k$ -forms  $P_{W_1}\alpha, \dots, P_{W_s}\alpha$  are basic and harmonic. Moreover, if  $\alpha$  is a basic  $k$ -form of type  $W$  so is the form  $\Delta_b \alpha$ .

## Theorem (M., R. Wolak)

*Let  $(M, \mathcal{F})$  be a compact Riemannian foliated manifold of codimension  $4q$ . If the foliation  $\mathcal{F}$  is cohomologically taut and transversely quaternionic Kähler then the basic Betti numbers  $B_{\mathcal{F}}^i$  of  $(M, \mathcal{F})$  satisfy the inequalities:*

$$B_{\mathcal{F}}^i \leq B_{\mathcal{F}}^{i+4} \leq \dots \leq B_{\mathcal{F}}^{i+4r}$$

*for  $i + 4r \leq q + 1$ ,  $i = 0, 1, 2$  or  $3$ .*

## Theorem (M., R. Wolak)

Let  $(M, g, Q, \mathcal{F})$  be a cohomologically taut quaternion Kähler foliated manifold of codimension  $4q$ . Then

- 1) for any  $k < q$  the linear map  $L: H^k(M, \mathcal{F}) \rightarrow H^{k+4}(M, \mathcal{F})$  is injective,
- 2) and there is the direct sum decomposition
$$H^k(M, \mathcal{F}) = \sum_{0 \leq s \leq [k/4]} L^s H_e^{k-4s}(M, \mathcal{F}), \quad k \leq q + 3.$$
